Adapter and withdrawal sleeves

Definition

Sleeves permit bearings with a tapered bore to be tightly fitted on cylindrical shafts of broad diameter tolerances. In general, the bore taper of such bearings is 1:12. However, spherical roller bearings of the 240.. and 241.. series have a bore taper of 1:30.

Two principal types of sleeve exist:

- Adapter sleeves, which generate a tight fit by driving the bearing along the sleeve.
- Withdrawal sleeves, which generate a tight fit by driving the sleeve into the bore of the bearing. The latter permit easy dismounting of the bearing by simple application of the appropriate withdrawal nut.

The quality of bearing installation and fit is fundamental to the achievement of long and reliable service. The cleanliness and suitability of the lubrication are also important factors.

■ Shaft tolerances for use with sleeve

Diameter tolerance: quality 9 minimum

Form tolerance: quality 5 minimum

Hydraulic sleeves: with large diameter bearings it is possible to use a hydraulic sleeve that is provided with ducts and distribution grooves thereby permitting the injection of pressurized oil between the bearing and sleeve, and between the sleeve and shaft.

	AH 241..		

Variants

The serie 2300 is available in inch.

Fitting and removal criteria

➔ Adapter sleeves

The sleeves are supplied complete with clamping nut and lock-washer. They comply with standard ISO 113/1.

➔ **Tightening the sleeves is a delicate operation, refer to the instructions to ensure satisfactory mounting.**

■ Fitting

▸ Mechanical method (1)

Lubricate the contact surfaces: by applying oil or grease to both the sleeve thread and the face of the nut which will be in contact with the bearing.

Tighten the nut until the required fits is obtained*.

Loosen and remove the nut in order to introduce the locking washer. Tighten the nut to reestablish the contact and lock it in place by bending one tab of the locking washer.

▸ Hydraulic method (2)

Lubricate the contact surfaces as per the mechanical method.

Screw the hydraulic nut onto the sleeve, its piston in contact with the bearing. Inject oil until the required fit is obtained*.

Remove the hydraulic nut, lock the sleeve with the locking washer.

▸ Heating method

After heating, fit the bearing onto the sleeve. Tighten the nut until the length of the thread exposed at the end of the sleeve is equal to the same length measured at room temperature plus required drive-up values*. Lock the nut in place with the locking washer. Induction heaters such as Fast Therm 20, Fast Therm 35 and Fast Therm 150.

* For control of clearance reduction due to fitting: see page 342.

Adapter and withdrawal sleeves *(continued)*

■ Removal

► Mechanical method (3)

Loosen the lock nut a few turns. Using a tubular drift, either against the lock nut or against the inner ring on the opposite face from the lock nut, carefully knock the bearing free.

► Hydraulic method (4)

Thread the hydraulic nut onto the sleeves. Take care to ensure the piston is facing away from the bearing. With a tubular « buffer » solidly mounted on the shaft against the piston of the hydraulic nut, inject oil until extraction of the sleeve.

Note: the inner ring must be stopped by an abutment on the shaft.

→ Withdrawal sleeves

The withdrawal sleeve is used in heavy assemblies where the bearings are difficult to handle and adjust. Its removal requires a nut (sold separately) which screws onto the sleeve and presses against one face of the bearing.

The standard taper of bearing bores and sleeves is 1:12 (except for series 240 and 241).

■ Fitting

► Mechanical method (5)

Lubricate the contact surfaces by applying oil to the sleeve and grease to both the sleeve thread and the face of the nut which will be in contact with the sleeve. Drive the sleeve up until the required fit is obtained*. Lock the sleeve in place on the shaft.

* For control of clearance reduction due to fitting: see page 342.

► Hydraulic method (6)

Lubricate the contact surfaces as per the mechanical method.

Lock the hydraulic nut in place on the shaft.

Inject oil until the required drive-up is obtained*. Lock the sleeve in place on the shaft.

► Heating method

At room temperature place the bearing on the shaft. Drive the sleeve up and tighten the shaft nut until contact is made. Measure the distance « D » between the nut face and the bearing inner ring face.

After heating the bearing, tighten the nut until the distance between nut face/inner ring face is equal to « D » minus the required drive-up*.

Induction heaters such as Fast Therm 20, Fast Therm 35 or Fast Therm 150 are recommended for controlled bearing heating.

■ Removal

The shaft must be equipped with an abutment in order to avoid injury due to a sudden ejection of the sleeve.

► Mechanical method (7)

Tighten the withdrawal nut onto the pre-greased thread of the sleeve until extraction is completed.

► Hydraulic method (8)

Thread the hydraulic nut onto the sleeve so that its piston faces the bearing. Inject oil until extraction is completed.

Suffixes

G

Modified thread for conformity to ISO standard 2982-1

* For control of clearance reduction due to fitting: see page 342.

Nuts and washers

Clamping and withdrawal nut

The clamping and withdrawal nuts (Standard ISO 2982) are used for axial locking of bearings with:

- cylindrical bore
- tapered bore

and for the extraction of a withdrawal sleeve.

When used for axial attachment, they are mounted with the corresponding tabwasher or locking stirrup with a suitable hexagonal head bolt, thereby making a simple low-cost and low-footprint clamping device.

Lock-washer (small dimensions)

The lock-washer (Standard ISO 2982) provides for positive locking of the clamping nut on the shaft. A groove has to be machined in the shaft if the lock-washer is used. The large number of tabs in the lock-washer enables the nut to be locked in the exactly right adjustment position.

Locking stirrup

This is a suitable system for large size nut safetying.

Self-locking precision nuts

Description

The self-locking precision nuts are assembly accessories that must be used in cases such as the following:

- When a preloading of the bearings package is required to guarantee the maintenance of the preloading time-value.
- When a high precision bearing assembly is being used, since this requires the use of accessories which will maintain the precision level of the equipment as a whole.
- When the setting of the position of the bearings package must be reliable and long-lasting, even when it is not preloaded (especially if the presence of significant axial efforts is foreseen during the operation of the equipment).

Overall, this type of nuts are used with ball bearings of angular contact (wether high precision or not), with cone bearings or with combined needle bearings.

Due to the high operating precision of these accessories due to an operation carried out on the equipment, at least whenever the nut has to be dismantled.

The self-locking precision nuts assure their position by means of two or four locking elements. These elements are grafts of softer material than steel, that are mechanized during the same operation as that of the interior thread of the nut and are then fitted into the thread of the axle. Nevertheless, this does not modify the perpendicularity of the lateral face of the nut in relation to the axle of the nut. The grafts are fixed to head screws with an inside hexagon, centered on these elements.

Series

■ Series with blind holes

■ Castellated series

The SNR range of precision self-locking nuts offers a complementary series whose difference lies in the tightening system. Tightening/locking is obtained by castellated design, instead of blind holes. The part numbers for these products are shown in the tables below.

Variants

Castellated series	Series with blind holes	Section	Number of inserts	Thread diameter	Material	Strength	Application
B	TB	Narrow	2	20 to 100 mm	High strength burnished steel	1 000 N/mm ²	Normal use
BR	TBR		4				Mean loads, maximum flatness requirement
BP	TBP	Wide	2				High loads
BPR	TBPR		4				Very high loads, maximum flatness requirement

Tolerances

The thread and the flat side of the nut which leans against the bearing are machined in the same fixation, which enables it to reach a high perpendicularity precision of: 0,005 millimeter tolerance.

The thread is in accordance with the rules ISO R/724 with a 5H tolerance and in accordance with ISO 965/1.

Design criteria

The unlocking momentum **M_d**, which is shown on the dimension tables for each type and size of nut is the power needed to apply to loosen this self-locking nut when it has been assembled previously by means of a tightening momentum **M_a**, and fixed via the tightening of the locking elements against the axle with a maximum tightening power of these elements **M_{bl}**, as shown in the tables.

The breaking axial load **F_{ar}**, also shown in the dimension tables, is the axial load which if applied to the nut will produce the breakage of the thread when it is assembled on an axle with a nut tolerance of 60. While operating, the maximum axial load which a nut can bear must be 75% of the breaking axial load **F_{ar}**, defined for such a nut.

Installation/assembly criteria

Since we are dealing with a high precision element, the nuts must be unwrapped until they are going to be used in order to avoid possible mechanical damage or dirt in the thread or on the push side.

They must lean on the covered side of the polished surface.

Once the thread is tightened with a spanner wrench (DIN 1810A and DIN 1810B), the fixation screws of the locking elements are tightened by use of an Allen wrench (for series containing four grafts, tightening these progressively crosswise).

SNR features a wide range of wrenches especially designed for your requirements.

Self-locking precision nuts (continued)
